

## MEDIUM ACCESS (DLL)

## ETHERNET LANS.

CSMA: Carrier Sense Multiple Access

RANDOM-ACCESS PROTOCOLS

↳ Schedule for transmission not decided in Advance

~~Random~~ → TDMA

TDMA: Time Division Multiple Access

## IDEA:

If node has data to send, create a frame & send it

BROADCAST → ALL NODES ON NETWORK ARE DESTINATION OF FRAME

UNICAST → SINGLE NODE IS DESTINATION OF FRAME

MULTICAST → A SUBSET OF NODES IS DESTINATION OF A FRAME (PACKET)

What if there is a collision?

A → B  
C → D at same time

1) COLLISION DETECTION - so that A & C know that a collision occurred

2) BACK-OFF FOR Random Time

3) CARRIER SENSE. If node has data to send, first sense the "medium" to see if a transmission is ongoing. Don't transmit if medium is busy

# IEEE 802.3

## CSMA-CD COLLISION DETECTION

### CARRIER-SENSE

If energy of signal > threshold  $\rightarrow$  conclude that channel is busy  
 $\downarrow$   
 larger than noise energy

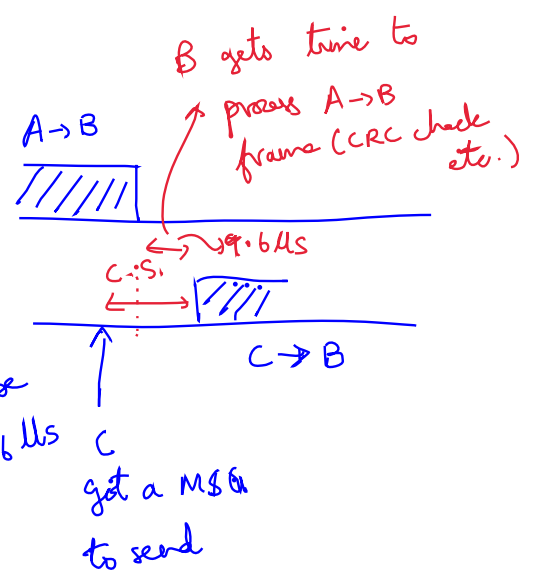

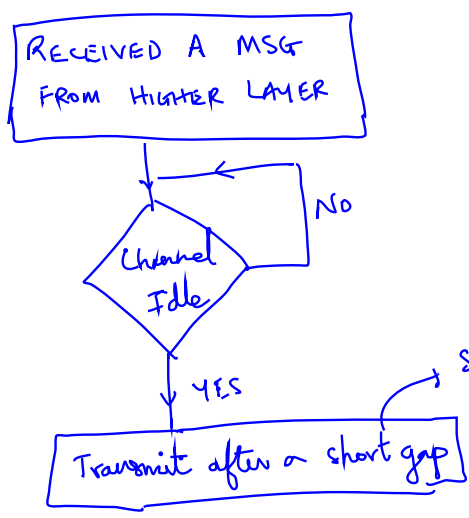

### COLLISION DETECTION

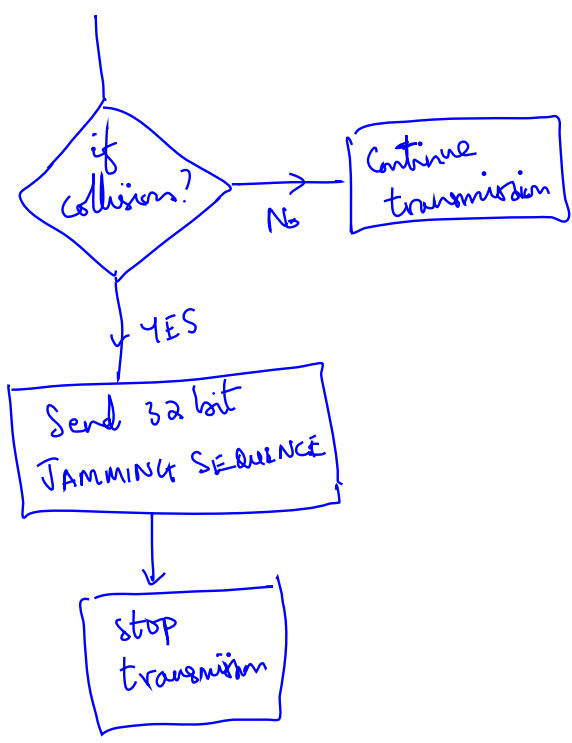

idea: Another threshold for collision detection (th2)  
 energy > th2 then collision

## Flow Chart

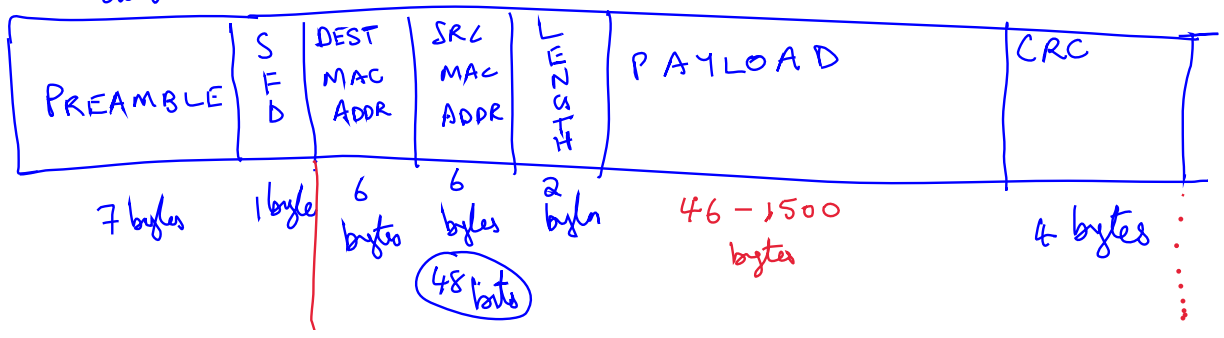

## COLLISION - DETECTION

## FRAME DETAILS IN 802.3

Start Frame Delimiter

2<sup>48</sup> → MAC address ; 2<sup>32</sup> → IPv4

Why min-frame size?

$$RTT = \frac{5000}{2 \times 10^8} = 25 \mu s$$

'A' must detect collision before his frame ends, if a collision occurs at the receiver

$\approx 50 \mu s$  RTT in worst case

64 bytes, 10Mbps transmission rate  $\rightarrow 51.2 \mu s$

MAX - FRAME SIZE

Large Frames

1) Higher prob. of getting a bit in error in frame

'p'  $\rightarrow$  suppose prob. of bit error

N  $\rightarrow$  frame length

Prob No error =  $(1-p)^N$   $\rightarrow$  assuming bit errors are independent

2) Others need to wait longer to get a chance to transmit

3) Memory requirements at NIC card go up.

Back-off

$\Delta$  - min wait time

Wait  $\in \Delta \cdot U.$

$\downarrow$   
 $\{0, 1, \dots, 2^K\}$

larger if more have collided.

Exponential back-off:

1st collision:  $K=1$ ;

2nd collision:  $K=2$

3rd:  $K=3$

10th:  $K=10$
